

DRAFT RESEARCH REPORT

SEPTEMBER 2005

The following is an extract from research conducted in July 2005 by

DR. IAN GILLAM
BSc (Hons), MSc, PhD, Dip Phys Ed, Cert Bus Management
MAAESS (ACP), FAAESS, FASMF.
Nutritionist and Exercise Physiologist

In collaboration with Associate Professor Steve Selig, Department of Human Movement, Performance and Recreation, Victoria University, Footscray Park Campus, Melbourne, Australia.

The samples included a male and a female triathlete. These subjects demonstrate the physical performance enhancement achieved by using the liquid oxygen supplement "Sports OxyShot" (which contains 150,000 parts per million of stabilised oxygen).

15ml dosages of Sports OxyShot were given to subjects and taken orally each morning for 7 days prior to testing.

15 ml dosages of a dummy placebo were similarly given and taken orally each morning for 7 days prior to testing.

The subjects received both the Sports Oxyshot and placebo dosages on a double blind crossover placebo basis, meaning neither the athletes nor the research teams knew which of the two trials included the Sports Oxyshot product.

Research Data for subject Mr. CH (a 23 year old elite triathlete) shows that the athlete turned over more oxygen and provided a higher workrate of approximately 6.1% at the an-aerobic threshold (4 mmol of whole blood lactate) during the bicycle ergometer work trial following the use of the Sports OxyShot. The 4 mmol of blood lactate is the point beyond which fatigue begins to shutdown physical exertion).

In addition, the benefit was seen to transfer across the disciplines (during the 7 day period on Sports Oxyshot), and resulted in a lifetime personal best time by over 5% for the 100 metres freestyle.

The times in the pool returned to the slower times during the 7 days on the placebo product (this subject was given the placebo on the second 7 day trial).

Although training during the Sports OxyShot treatment was reported to have been completed with less effort and fatigue, an increase in the exercise heart rate and the perceived exertion was reported during the bicycle work trial (to exhaustion) by a margin consistent with the increased work rate.

Data for subject DG (40 year old Female Master Triathlete)

It demonstrates an interesting relationship between the oxygen uptake at the an-aerobic threshold (a 3.75 % increase when on Sports OxyShot) and the increased oxygen uptake at the aerobic threshold of 7% (about 100% more benefit at the steady state exercise level).

The higher oxygen uptake (resulting from using Sports Oxyshot) at lower levels of exercise may prove very beneficial to recreational athletes (gym and “spin class”) who would relish the corresponding increase in oxygen/calorie expenditure, without having to push super hard to achieve this.

For the serious athlete on race day however the 3.7% increase of oxygen uptake at the an-aerobic threshold would result in an improved race time of approximately 3 minutes per hour over the course of the Forster Ironman. This would reduce her previous best time of 13 hours by about 33 minutes. Naturally, several ‘housekeeping’ issues would have to be addressed:

1. The Sports Oxyshot supplement would need to be maintained, possibly 1 0ml per 60 minutes (not with food)
2. As the calorie expenditure is being increased by approximately 3.7%, it would require additional food and water to be consumed, at periods when the Sports OxyShot is not being consumed.
3. Given the higher perceived exertion and heart rates, only the truly committed athlete is likely to continue at such an elevated intensity level. In other words, courage and determination will be rewarded. Fortune favours the brave!

EXPLANATORY NOTES

THE WORK TRIAL

Subjects were randomly allocated either Sports Oxyspot or Placebo (flat diet tonic water) and given an unlabelled bottle to consume a 15 ml shot on each morning in the week prior to testing. Athletes were requested not to train 12 hours prior to each test and to control their diet (i.e. same meals), on the day and morning prior to each test. Exercise tests were conducted one week apart and each subject performed each test at the same time of day for each trial. Testing was conducted at the Human Performance Laboratory at Victoria University under standardized conditions.

An electromagnetic bicycle ergometer was used to conduct the exercise tests and after a 3 minute warm up at 50 watts, subjects completed an incremental exercise test until they were exhausted. The test began at 100 watts and was increased by 25 watt increments every two minutes until they were exhausted. Metabolic measurements (Oxygen uptake, RER, VE ETC) were measured every 30 seconds, heart rates were measured using an ECG and capillarized lactate was measured in the last 15 seconds of each workload.

The results are outlined in the following graphs. Figures 3 to 5 show the blood lactate levels, indicated on the vertical axis and measured in millimol of whole blood lactate.

The 2 mmol level is referred to as the aerobic threshold, the level at which steady state exercise can be maintained for extended periods (providing that high intensity exercise is not attempted) and reflects the status where oxygen is metabolised within the energy systems at an optimal sustainable level. The 4 mmol level is referred to as the an-aerobic threshold and marks the limit of physical activity where oxygen can be delivered in sufficient quantities to maintain the desired work rate. Beyond the an-aerobic threshold the inability to deliver sufficient oxygen results in the rapid onset of fatigue.

The legend used in the following figures is: **OS = Sports Oxyspot, PL = Placebo**

Interpretation notes for figures 1 – 6.

NOTE:

Subject

- (a) CH 23 Year old male elite triathlete
- (b) DG 40 year old female masters iron man triathlete

- Figures 1 +2 Provide a summary of eleven different parameters and the researchers' observations along with the objective comments of analysis, and general recommendations.
- Figure 3 Compares oxygen uptake against blood lactate, with clearly a significant increase in the level of oxygen metabolized: by 6.1% in the case of the male athlete and 3.7% for the female athlete during the Sports OxyShot trial versus the placebo trial. It is on figure 3B that the 7% increase in oxygen uptake at the aerobic threshold is observed in the female athlete.
- Figure 4 Compares power output against blood lactate and shows an increase in power output at the an-aerobic threshold of 3.5% for the male and 2.2% for the female athlete (after using Sports OxyShot).
- Figure 5 Relates to a corresponding increase in heart rate of 4% for the male and 2.2% for the female athlete consistent with the higher work rates and oxygen uptake.
- Figure 6 Shows the perception of increased intensity felt and reported by the athletes, which confirms that 'something' is helping them 'do more work'.
- Figure 7 A one-page summary (The results at a glance)

**Figure 2A Sports OxyShot Project
Data Summary**

Subject CH Male Elite Triathlete
 Age 23 yrs
 Weight 64.25kg
 Skinfold Total (8) 61.2mm
 Maximal Data

Parameter	Placebo	Sports OxyShot	Difference
VO2 peak (L/min)	4.90	4.96	+1.3%
VO2 peak MI/kg/min	76.2	77.2	+1.3%
Peak Power (watts)	389	394	+1.2%
Exercise time to Exhaustion (mins)	28	28	0
Max Heart Rate (bpm)	192	192	
Max Ventilation (L/min)	161	165	+2.4%
MaxRER	1.08	1.07	

Comments

1. Small but consistent increase in Oxygen Uptake and power output at 4 mM Lactate threshold (4-6%) and an increased steady state exercise heart rate at 4mM threshold (4%), following treatment with Sports OxyShot. This should translate into improved times during a triathlon (assuming the cycling test is equally applicable to swim and run performances) of around 3 mins/hour during the event.
2. During the week the subject consumed the Sports Oxyshot a definite improvement was noticed in the swim times. Performance was improved from 1 min 11 secs to 1 :07/100m freestyle (which had not previously been achieved), which returned to the slower times during the following week while on placebo. Training was also completed with less effort and fatigue.
3. Surprisingly, during the exercise tests the relative perceived exertion (RPE) was higher on Sports Oxyshot than placebo at each of the power outputs.
4. There was minimal increase in peak VO2 and any of the other maximal performance data measured.
5. Recommended training heart rates:
 - a) Long slow distance (<2mM Threshold) <135 bpm
 - b) Quality aerobic training 145– 155 bpm
 - c) Lactate threshold training (@4mM thresh) 155– 168 bpm
 - d) Speed and anaerobic training > 170bpm
6. It was recommended that the skinfold total be reduced to 45 mm and a weight goal of around 62 kg was desirable.

Comments

1. Small but consistent increase in Oxygen Uptake and power output at 4mM lactate Threshold (4-5%) and an increased steady state exercise heart rate at 4mM threshold (2.2%), following treatment with Sports OxyShot. This should translate into improved times during a triathlon (assuming the cycling test is equally applicable to swim and run performances) of around 3 mins/hour during the event.
2. Small moderate increase in Oxygen Uptake and power output at 2mM Lactate Threshold (7-25%) and an increased steady state exercise heart rate at 4mM threshold (5%), following treatment with Sports OxyShot.
3. Surprisingly, during the exercise tests the relative perceived exertion (RPE) was higher on Sports Oxyshot than placebo at most power outputs, except those at near maximal exercise (there may be gender related issues).
4. There was a small decrease in peak VO2 (2-3%) and the other maximal performance data measured.
5. Recommendation training heart rates.

a) Long slow distance (<2mM Threshold)	140– 150 bpm (need to increase this as your LSD training HR appears to be too low for effective training)
b) Quality aerobic training	150-165 bpm
c) Lactate threshold Training (2-4mM Thresh)	165– 175 bpm
d) Speed and anaerobic training	> 175 bpm
6. It was recommended that the skinfold total be reduced to 80 mm and a weight goal of around 65 kg was desirable.

THE RESULTS AT A GLANCE

Comparison in V02's between Sports Oxyspot and placebo trials at the 4mM HLa Threshold

SUBJECT	PL V02 (ml/min)	OS V02 (ml/min)	% Difference
CH	3700	3925	+ 6.1%
DG	3490	3620	+ 3.7%

Comparison in Power Output's between Sports Oxyspot and placebo trials at the 4 mM HLa Threshold.

SUBJECT	PL Power (Watts)	OS Power (Watts)	% Difference
CH	283	293	= 3.5%
DG	175	179	+ 2.2%

Maximal Exercise Data

There was no increase in the Peak oxygen uptake (V02 peak) or peak Power following treatment of Sports Oxyspot.

Comparison in V02 peaks (in ml/kg/min) between Sports Oxyspot and placebo trials.

SUBJECT	PL V02 peak (ml/min)	OS V02 peak (ml/min)	% Difference
CH	76.2	77.2	+ 1.3%
DG	58.3	57.3	- 2.3%

Comparison in Power peaks (in watts) between Sports Oxyspot and placebo trials.

SUBJECT	PL Power peak (watts)	OS Power peak (watts)	% Difference
CH	389	394	+1.2%
DG	311	303	- 2.6%
